EVALUATING RECONFIGURATION IMPACT IN SELF-ADAPTIVE SYSTEMS AN APPROACH BASED ON COMBINATORIAL INTERACTION TESTING

August 27, 2015 12h30-12h45, SEAA 2015, Funchal Madeira

OUTLINE

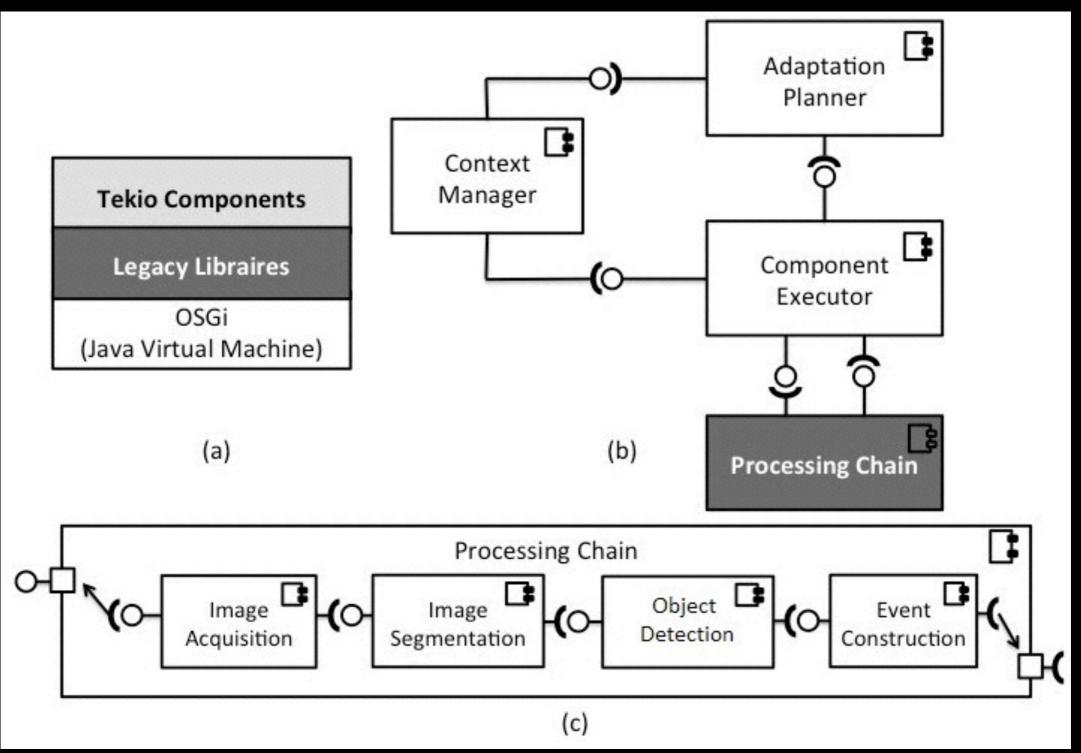

- problem context
- approach to generate test sequence of reconfigurations
- preliminary validation
- what impact can this work have?

TEKIO: A SELF-ADAPTIVE VISION SYSTEM

Software system that adapts due to change in operational context

TEKIO'S ARCHITECTURE

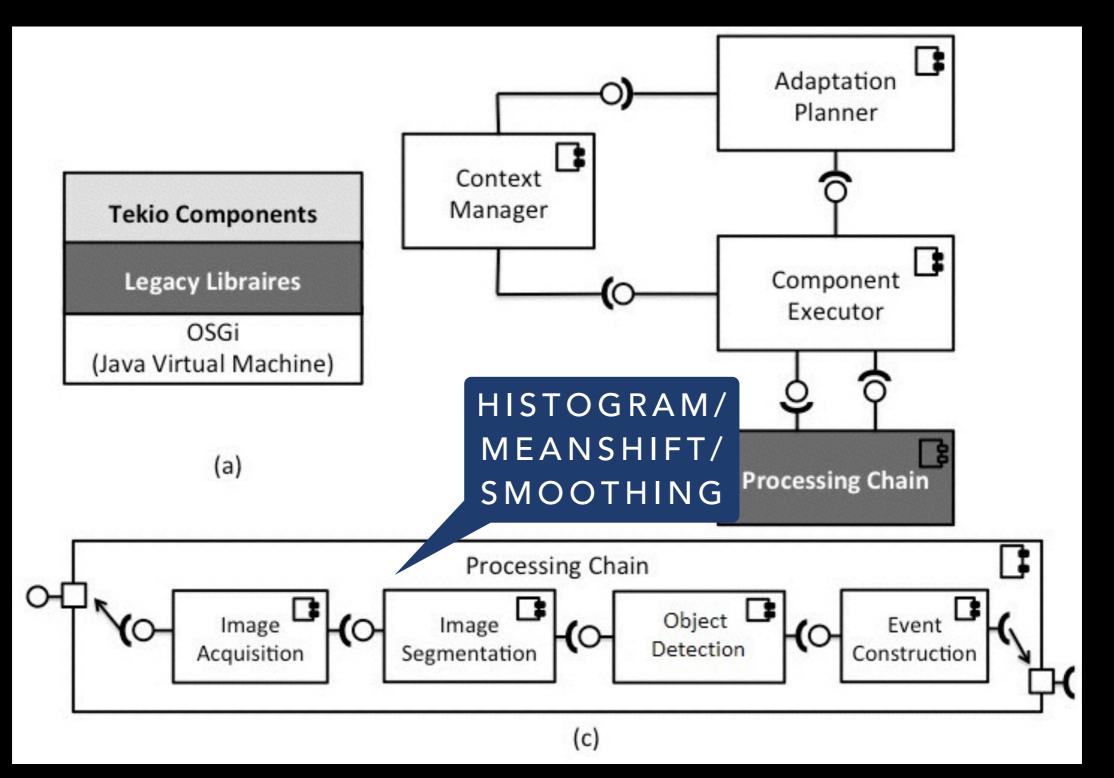

Santiago Hurtado, Sagar Sen, and Rubby Casallas. 2011. Reusing legacy software in a selfadaptive middleware framework. (ARM '11). ACM, New York, NY, USA, 29-35.

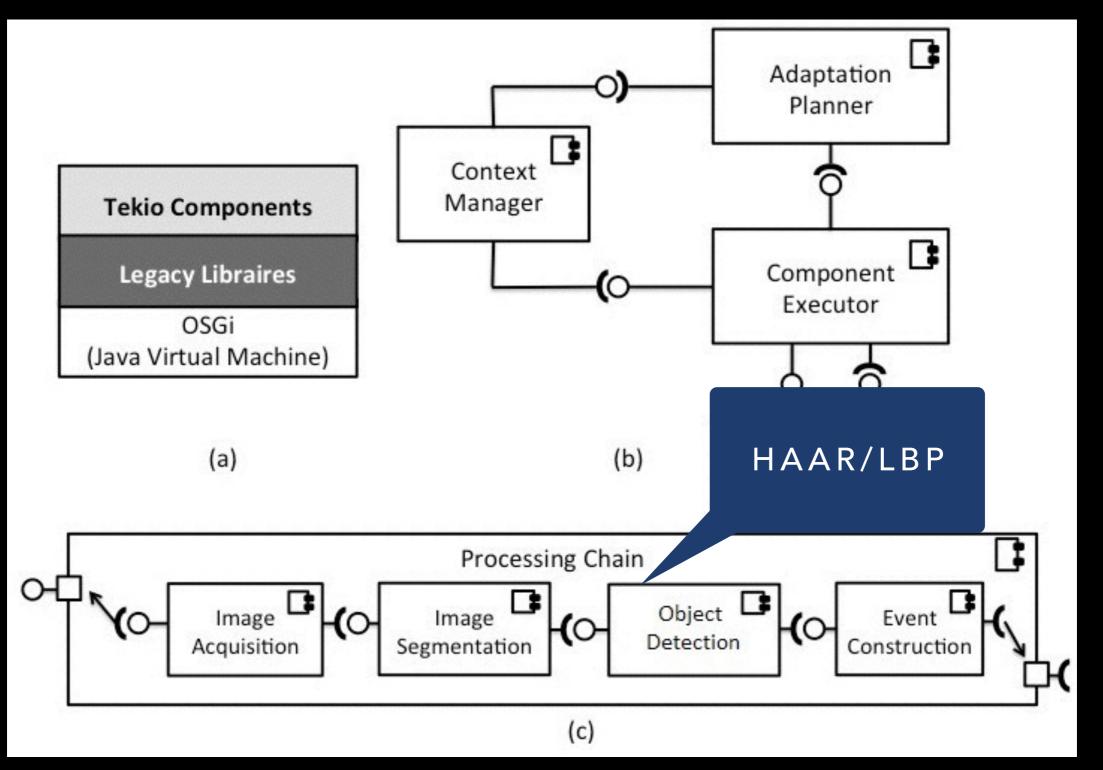

SEVERAL POSSIBLE WAYS TO CONFIGURE

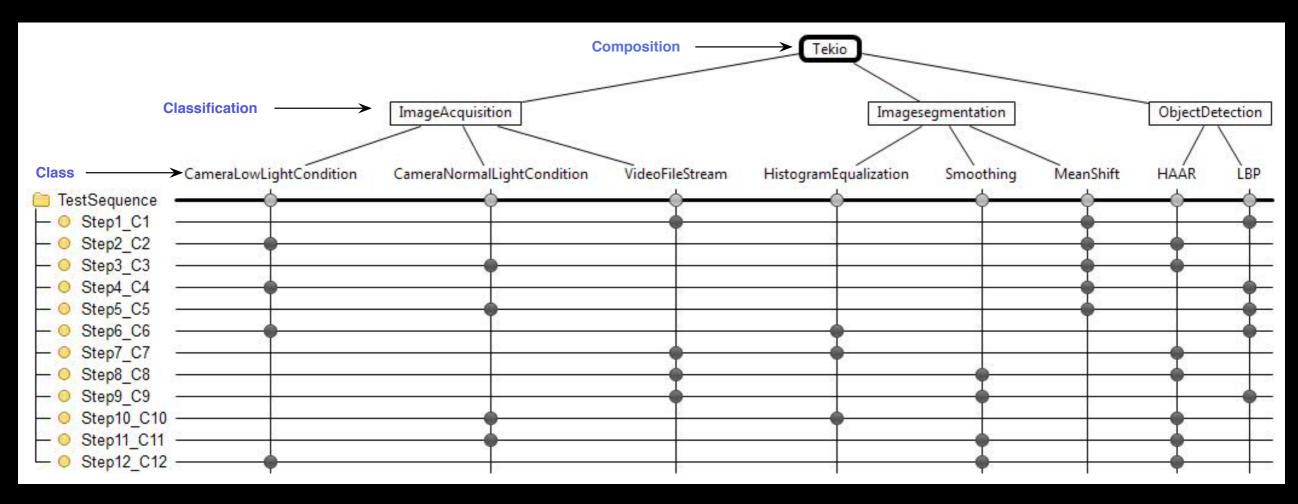

SEVERAL POSSIBLE WAYS TO CONFIGURE

SEVERAL POSSIBLE WAYS TO CONFIGURE

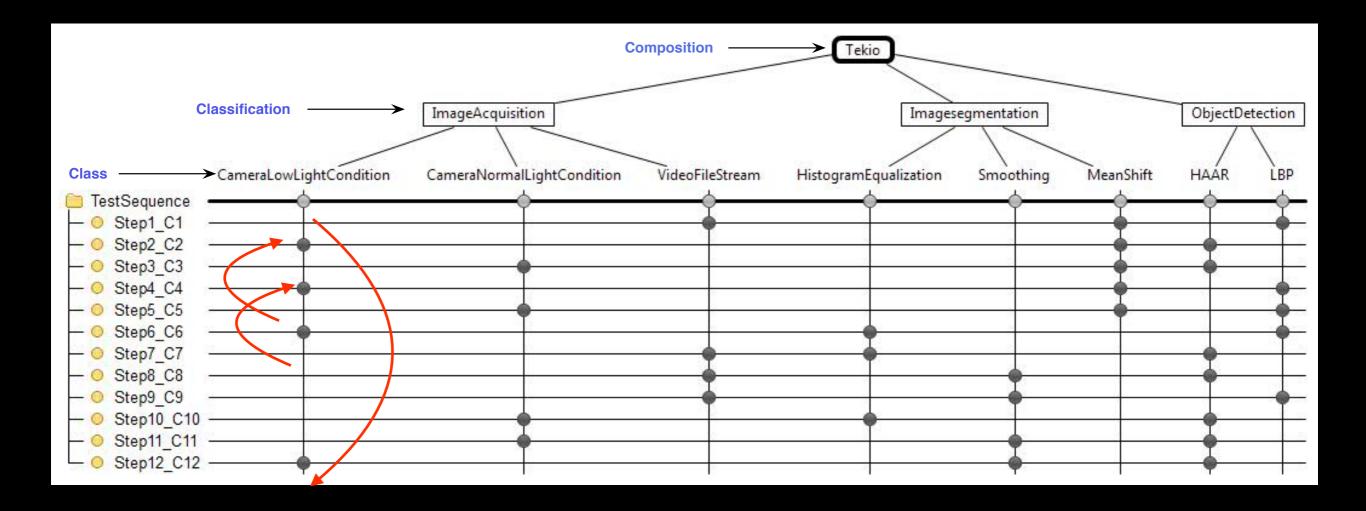

MODELLING VARIABILITY WITH CLASSIFICATION TREES

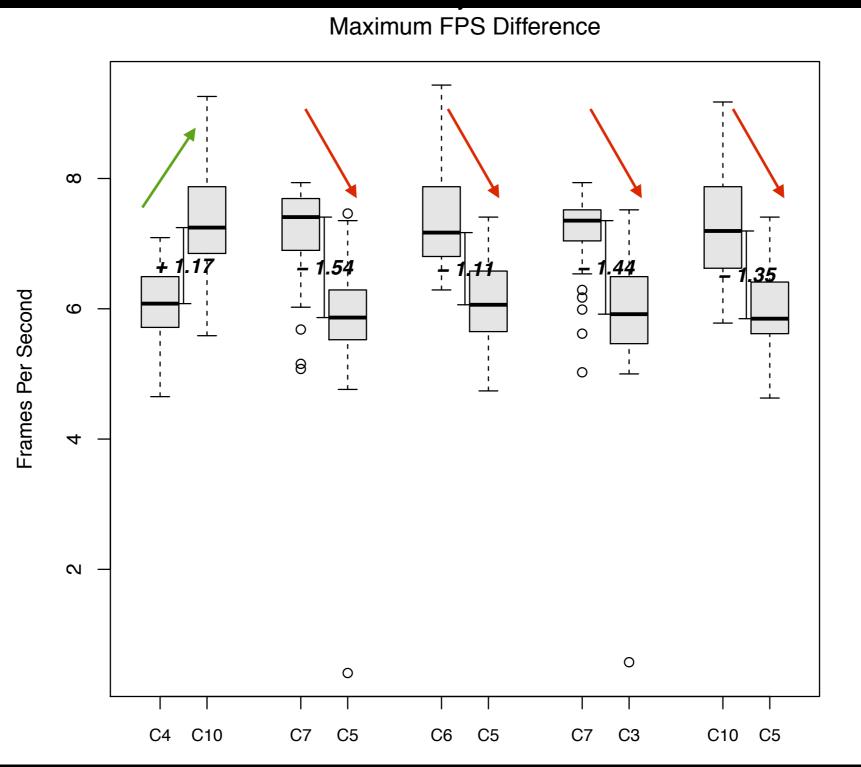

configurations

• What can happen when we **arbitrarily reconfigure** the self-adaptive system based on contextual changes?

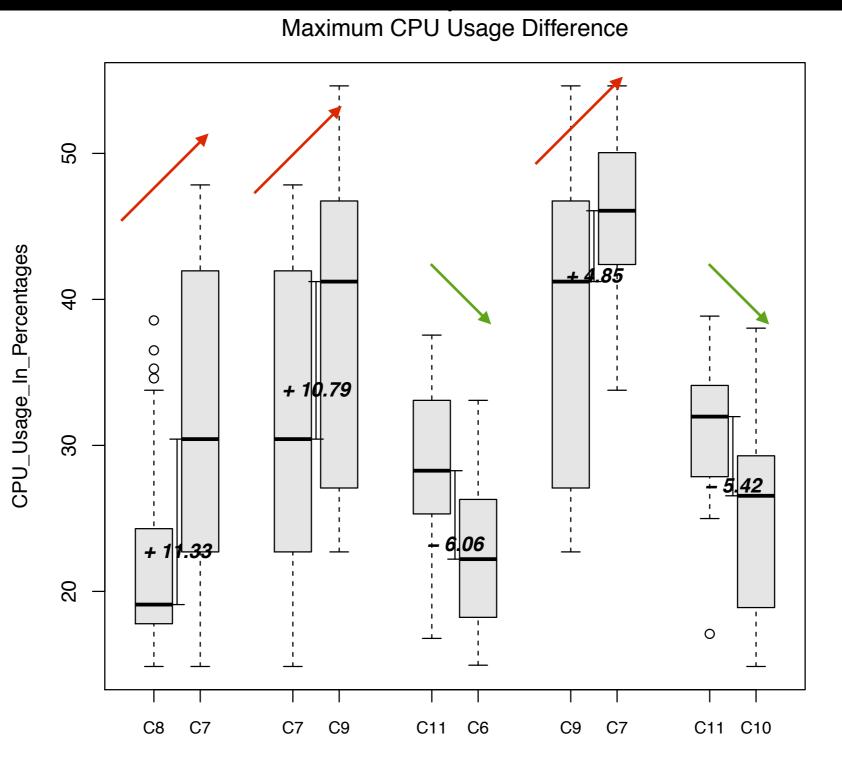

RECONFIGURATION

IMPACT ON QOS (FRAME RATE)

IMPACT OF QOS (CPU USAGE)

Test Configuration Adaptation Pairs

CHALLENGE

 How can we generate an adequate test sequence of reconfigurations such that we can understand and evaluate reconfiguration impact on QoS?

OUTLINE

- a challenge in testing self-adaptive systems
- approach to generate test sequence of reconfigurations
- preliminary validation
- what impact can this work have?

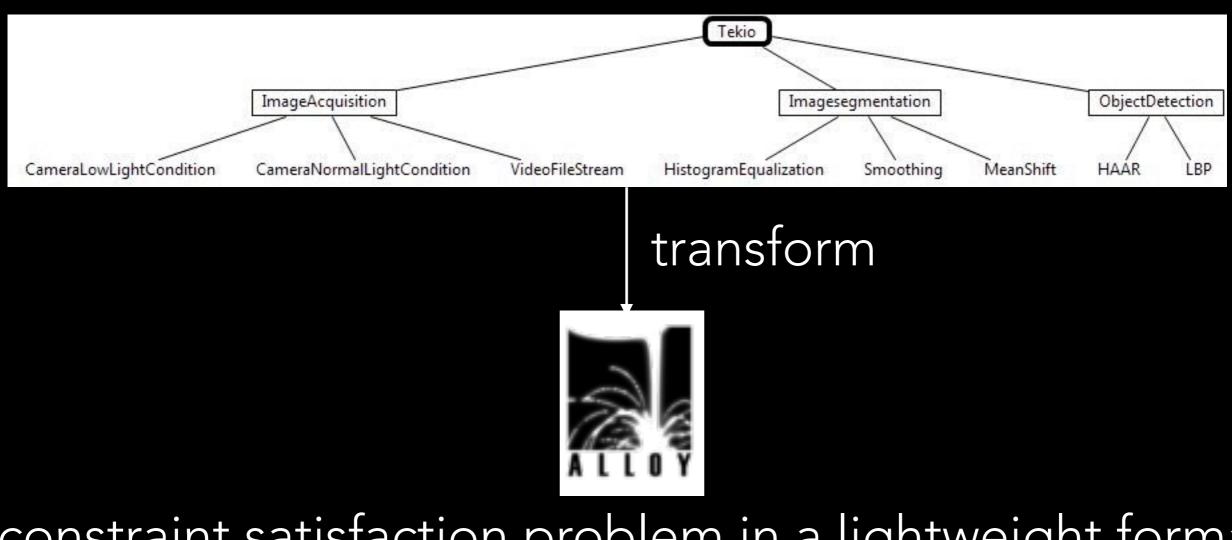

CONDITIONS FOR THE TEST SEQUENCE ADEQUACY

- It is a minimal sequence of repeated configurations of an adaptive system
- Configurations in the sequence must cover **T-wise** (pairwise in most cases) interactions between variable/mutable features. Eg. interaction between object detection and image segmentation
- Sequence must satisfy constraints between adaptable features (such as only one of two possible object detection algorithms can be used in a configuration)
- The sequence must cover all valid **R-wise interactions** (hops) between configurations.

Step 1: Generating **configurations** covering T-wise interactions

TRANSFORMATION OF CLASSIFICATION TREE TO ALLOY

constraint satisfaction problem in a lightweight formal method Alloy

ALLOY

- The Alloy language can represent a modelling domain such as classification trees in **first-order relational logic with quantifiers.**
- Alloy signatures define a finite set of "atoms" immutable named entities.
 Eg. The signature Integer has atoms -2,-1,0,1,2,...etc. in the a finite scope of 2.
- Alloy facts, predicates, and functions specify constraints between atoms as "relations". Eg. The relation "xor" between two signatures is a 2-tuple relation
- Alloy Analyser transforms a modelling domain to 3-Conjunctive Normal Form to be solved by a SAT solver such as MiniSAT in a finite scope. The solver create atoms in the scope and determines an assignment for all relations called an Alloy instance.
- Alloy instances can then be transformed back to a a set of configurations

HIGHLIGHTS OF TRANSFORMATION

- **Features** of the adaptive system are Alloy signatures
- A Configuration signature is a relation towards a set of features
- A ConfigurationSet signature is relation to a set of configurations
- Constraints between features are transformed to Alloy facts
- T-wise combinatorial interactions between features are transformed to a set of 2^T C(N,T) Alloy predicates (Details of transformation in the paper)

- Goal is to solve the Alloy model to obtain a ConfigurationSet
- With a minimal number of configurations that satisfies all valid T-wise interaction predicates
- Intractable

INCREMENTAL GROWTH OF CONFIGURATION SET

- We **incrementally grow** configuration sets until all T-wise predicates are solved in a **finite scope.**
- We merge all configuration sets into a one set of configurations that cover all T-wise predicates.

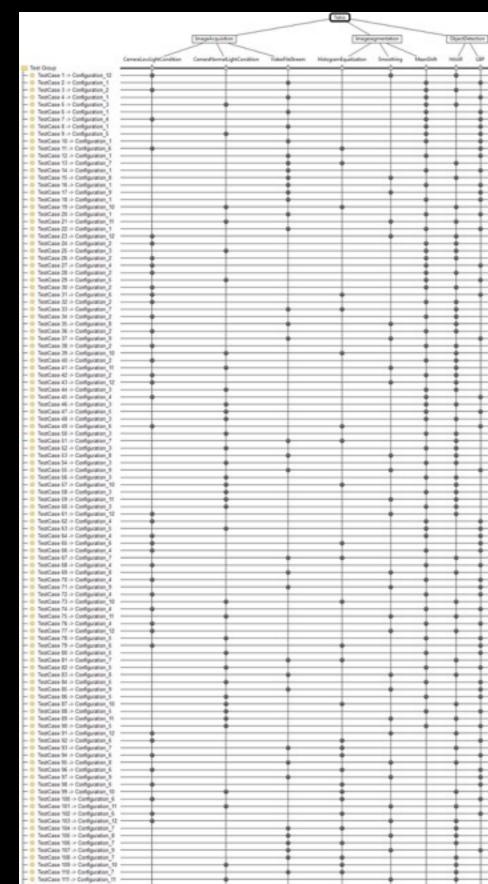

Step 2: Generating a **test sequence** covering R-wise hops between configurations from Step 1

TEST SEQUENCE THAT COVERS ALL R-WISE

- Given a set of K configurations that cover T-wise interactions between features we generate all Rpermutations of the set of K configurations.
- Test sequence satisfying all R-wise permutations contains K!/(K-R)! reconfigurations

RESULT LOOKS LIKE THIS FOR TEKIO

132 Reconfigurations covering all pairwise feature interactions and pairwise reconfigurations between configurations for Tekio

OUTLINE

- a challenge in testing self-adaptive systems
- approach to generate test sequence of reconfigurations
- preliminary validation
- what impact can this work have?

PRELIMINARY VALIDATION

- We measured CPU Usage, Frame rate, and Memory usage in Tekio by running the sequence of 132 reconfigurations about 100 times
- We discovered several critical reconfigurations that consistently led to fluctuations in CPU usage and frame rate.
- These reconfigurations eventually helped develop adaptation rules for stable QoS

OUTLINE

- a challenge in testing self-adaptive systems
- approach to generate test sequence of reconfigurations
- preliminary validation
- what impact can this work have?

IMPACT

- (Self-)adaptive component-based systems empower software reuse and evolution and change behaviour at runtime
- However, this comes the "cost" of unknown and unexpected behaviour
- We aim to tame this unpredictability by understanding reconfiguration impact with combinatorial interaction testing
- **Combinatorial interaction testing** gives good **coverage** of behaviour and is successful in detecting unpredictability
- Not much better than random testing

Thank you! <u>sagar@simula.no</u>
